Diagnosing and Treating

MYALGIC ENCEPHALOMYELITIS/CHRONIC FATIGUE SYNDROME (ME/CFS)

– U.S. ME/CFS CLINICIAN COALITION –

August 2019

About the U.S. ME/CFS Clinician Coalition

The U.S. ME/CFS Clinician Coalition is a group of US clinical disease experts who have collectively spent hundreds of years treating many thousands of ME/CFS patients. They have authored primers on clinical management, have served on CDC medical education initiatives, and are actively involved in ME/CFS research. Members of this group include:

Dr. Lucinda Bateman - Internal Medicine, UT
Dr. Theresa Dowell - Family Nurse Practitioner, AZ
Dr. Anthony Komaroff - Internal Medicine, MA
Dr. Nancy Klimas - Immunology, FL
Dr. Ben Natelson - Neurology, NY
Dr. Richard Podell - Internal Medicine, NJ
Dr. Alison Bested - Hematological Pathology, FL
Dr. Susan Levine - Infectious Disease, NY
Dr. David Kaufman - Internal Medicine, CA
Dr. Charles Lapp - Internal Medicine & Pediatrics, NC
Dr. Dan Peterson - Internal Medicine, NV
Dr. Irma Rey – Internal & Environmental Medicine, FL

If you are a US clinician and want more information, please contact us at https://forms.gle/kf2RWSR2s1VqF6uy7
DIAGNOSING ME/CFS

Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a complex, chronic, debilitating disease that affects millions of people worldwide but is often undiagnosed or misdiagnosed. To improve diagnosis, the National Academy of Medicine (NAM) established new evidence-based clinical diagnostic criteria in 2015.

PRESENTATION AND RECOGNIZING THE DISTINCTIVE SYMPTOMS OF ME/CFS

The onset of ME/CFS is often sudden. Frequently, patients report that an infectious-like syndrome or infectious disease (such as infectious mononucleosis or flu-like illness) preceded the onset of their disease. Diagnosis requires a thorough medical history, a physical exam, and recognition of the following core symptoms:

- Substantial reduction or impairment in the ability to engage in pre-illness activity that persists for 6 months or more and is accompanied by fatigue. The fatigue is profound, not lifelong, not the result of ongoing exertion, and not alleviated by rest.
- Post-exertional malaise (PEM) in which physical or mental activities result in a typically delayed and prolonged exacerbation of symptoms and reduction in functioning (discussed further below).
- Unrefreshing sleep and a variety of sleep disturbances
- Either cognitive impairment and/or orthostatic intolerance (the development of symptoms when upright that are alleviated when lying down)

These core features of illness must be moderate to severe and present at least 50% of the time; this is key to separating ME/CFS from other common causes of chronic fatigue. PEM is the clinical hallmark of ME/CFS and its most distinctive symptom. PEM can help differentiate ME/CFS from other conditions and has been objectively associated with impaired aerobic energy metabolism and orthostatic stress.

Other ME/CFS symptoms include widespread pain; additional forms of sleep disturbance; light, noise, and chemical sensitivity; sore throat; tender lymph nodes; headaches; gastrointestinal problems; and genitourinary issues. The NAM Clinician’s Guide provides further explanation and guidance on how to identify both core symptoms and additional symptoms (see references at the end).

IDENTIFYING THE HALLMARK POST-EXERTIONAL MALAISE (PEM)

Patients experiencing PEM will often describe a “crash,” “relapse,” or “collapse” after even small amounts of mental or physical exertion that was previously tolerated. During the crash, which may be immediate but more often delayed by hours or days, patients can experience an exacerbation of one or all of their symptoms and a further reduction in functioning. It can take hours, days, a week or even longer to return to their previous baseline after a crash. Some patients may go through cycles of overexerting and crashing while others may have learned to reduce or change activities to minimize crashes. For some patients, even basic activities of daily living can result in PEM.

The Following Questions May Help Identify Whether A Patient Experiences PEM:

* What happens when you engage in normal (previously tolerated) physical or mental exertion?
* How much activity does it take to make you feel ill or to trigger illness worsening?
* How long does it take to recover from this physical or mental effort?
* Do you avoid or change certain activities because of what happens after you do them?

It may help patients and clinicians to identify PEM if patients keep a daily diary of their symptoms and activities for two weeks.
**DIAGNOSTIC TESTS**

While research studies have demonstrated numerous differences in biological measurements in ME/CFS, there is not yet a test validated for the diagnosis of ME/CFS in clinical practice. But there are many diagnostic tests to help identify other fatiguing illnesses or comorbid conditions that are often found in people with ME/CFS. For example, orthostatic intolerance can be assessed with a NASA Lean Test (standing test) or a tilt table test for 10-20 minutes or up to 30 minutes for neurally mediated hypotension (see Rowe 2014). Beyond helping to establish a diagnosis, tests can also be important in developing treatment plans to address comorbid conditions. Disease experts may also use lab tests to identify issues such as immune impairment to guide treatment but these are more typically used by specialists and in research.

**THE IMPORTANCE OF DIFFERENTIAL DIAGNOSIS**

Some of the symptoms of ME/CFS are also observed in healthy people as well as people affected by other illnesses. Appropriate treatment of these other conditions may completely resolve the patient’s symptoms. Thus, it is important to distinguish between ME/CFS and these other conditions. Important diseases in this category include but are not limited to the following:

<table>
<thead>
<tr>
<th>ENDOCRINE/METABOLIC DISORDERS</th>
<th>RHEUMATOLOGICAL DISEASES</th>
<th>NEUROLOGIC DISORDERS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary Adrenal Insufficiency, Hypercortisolism, Hyper- and Hypothyroidism, Diabetes, Hypercalcemia</td>
<td>Systemic Lupus, Rheumatoid Arthritis, Polymyositis, Polymyalgia Rheumatica</td>
<td>Multiple Sclerosis, Parkinson’s Disease, Myasthenia Gravis, Vitamin B12 deficiency, Cerebrospinal Fluid Leak, Chiari Malformation, Traumatic Brain Injury, Spinal Stenosis, Craniovertebral Instability, Seizures</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>INFECTIOUS DISEASES</th>
<th>SLEEP DISORDERS</th>
<th>PRIMARY PSYCHIATRIC DISORDERS</th>
</tr>
</thead>
<tbody>
<tr>
<td>HIV, Tick Borne Diseases, Hepatitis B/C, TB, Giardia, West Nile Virus, Q-fever, Valley Fever, Syphilis, Epstein-Barr Virus, Parvovirus</td>
<td>Sleep Apnea, Narcolepsy, Periodic Limb Movement Disorder</td>
<td>Anxiety, Depression, Bipolar Disorder</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>GASTROINTESTINAL DISORDERS</th>
<th>CARDIOVASCULAR DISORDERS</th>
<th>HEMATOLOGICAL DISORDERS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Celiac Disease, Food Allergy or Intolerances, Inflammatory Bowel Diseases, Small Intestinal Bacterial Overgrowth</td>
<td>Cardiomyopathy, Coronary Artery Disease, Pulmonary Hypertension, Valvular Heart Disease, Arrhythmias</td>
<td>Anemia (iron deficiency, other treatable forms), Iron Overload</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>TOXIC SUBSTANCES</th>
<th>MALIGNANCY</th>
<th>OTHER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Substance Abuse, Environmental exposures (e.g. lead, mercury), Mold/Mycotoxins, Adverse medication effects, Gulf War Illness</td>
<td>Primary and Secondary Cancers</td>
<td>Severe Obesity (BMI &gt; 40), Overwork, Athletic Overtraining Syndrome, Asthma, Chronic Obstructive Pulmonary Disease</td>
</tr>
</tbody>
</table>

Note: The underlined conditions are those that are also commonly comorbid with ME/CFS
IDENTIFYING COMMONLY COMORBID CONDITIONS

In the past, a diagnosis of ME/CFS was made by first excluding all other possible conditions. However, the 2015 National Academy of Medicine report established ME/CFS as a positive diagnosis that can coexist with other conditions, including those in the differential diagnosis. Recognizing co-morbid conditions early and treating them appropriately may improve the patient’s health, function, and quality of life. Commonly comorbid conditions include:

<table>
<thead>
<tr>
<th>AUTONOMIC DYSFUNCTION</th>
<th>RHEUMATOLOGICAL DISORDERS</th>
<th>NEUROLOGICAL DISORDERS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Postural Orthostatic Tachycardia Syndrome (POTS), Neurally Mediated Hypotension (NMH), Orthostatic Hypotension</td>
<td>Fibromyalgia, Ehlers-Danlos Syndrome, Temporomandibular Joint Dysfunction, Sicca Syndrome (dry eyes/mouth)</td>
<td>Hypersensitivities (light, sound, touch, odors or chemicals), Poor Balance, Migraine Headaches, Peripheral Neuropathy, Small Fiber Neuropathy</td>
</tr>
<tr>
<td>IMMUNE</td>
<td>GASTROINTESTINAL DISORDERS</td>
<td>ENDOCRINE/METABOLIC DISORDERS</td>
</tr>
<tr>
<td>New or worsened allergies, Mast Cell Activation Syndrome, Multiple Chemical Sensitivities, Chronic infections &amp; immunodeficiencies</td>
<td>Food Allergy and Intolerances, including to milk protein, Gut motility issues, Celiac Disease, Irritable Bowel Syndrome, Small Intestinal Bacterial Overgrowth</td>
<td>Hypothyroidism, HPA Axis Dysregulation (low normal or flattened cortisol curve), Metabolic Syndrome</td>
</tr>
<tr>
<td>SLEEP DISORDERS</td>
<td>PSYCHIATRIC DISORDERS</td>
<td>GYNECOLOGICAL DISORDERS</td>
</tr>
<tr>
<td>Sleep Apnea, Restless Leg Syndrome, Periodic Limb Movement Disorder</td>
<td>Anxiety, Depression</td>
<td>Endometriosis, Premenstrual Syndrome, Vulvodynia</td>
</tr>
<tr>
<td>OTHER</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interstitial Cystitis, Overactive Bladder, Nutritional deficiencies, Vitamin B12 and D deficiencies, Obesity</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
TREATING AND MANAGING ME/CFS (THE BASICS)

In the past, ME/CFS has been characterized as a syndrome of medically unexplained fatigue responsive to talk therapy and graded exercise. But scientific advances are revealing a complex, multisystem disease involving neurological, immunological, autonomic, and energy metabolism impairments. There is a critical need for a different approach to management of the disease and accompanying comorbidities.

1. Validate the patient experience and educate about the disease

Patients may have experienced skepticism about their disease. The most important thing that a medical provider can do is to validate the illness for the patient and the patient’s family. Explain that ME/CFS is a serious medical illness and is not laziness, depression, or a psychosomatic disorder.

2. Address impaired function and provide support as needed

By definition, patients with ME/CFS have significant disability. Patients may need help in obtaining accommodations for school and work or when applying for disability. They may also need parking permits, assistive devices, and/or home health aides. Because of the financial impact, some patients may need help with shelter and food. Many may also lose their health insurance.

3. Educate patients about pacing to prevent or minimize PEM

An important role for the medical provider is to teach patients about PEM and how to manage it with pacing. Pacing is an individualized approach to managing physical, cognitive, and emotional energy within a patient’s specific limits by carefully planning where and how to spend their available energy. It is a critical tool to prevent and/or reduce PEM. Activity logs and heart rate and activity monitors can be used to help patients understand when they are overdoing their specific energy limits. Even with such aids, pacing is a challenging task and some setbacks are inevitable, especially since tolerance for activity can vary from patient to patient and day to day.

4. Treat/manage symptoms (*)

While there are no treatments approved specifically for ME/CFS, a number of different pharmacological and non-pharmacological treatments can help reduce the severity of symptoms. Some examples of commonly used medications include low-dose naltrexone, duloxetine, gabapentin, or pregabalin for pain; fludrocortisone, midodrine, pyridostigmine, low dose beta-blockers and/or intravenous hydration for orthostatic intolerance; occasional use of modafinil, methylphenidate, or dexedrine for cognitive or fatigue issues; and trazodone, clonazepam, tricyclic antidepressants, or suvorexant for sleep. Drugs should be started at low doses and increased slowly to avoid triggering drug sensitivities common in ME/CFS.

Non-pharmacological approaches include: salt and fluid loading and compression stockings for those with orthostatic problems; cognitive aids (e.g. writing notes to assist memory; keeping a calendar, notebook and calculator at hand; and always placing important items in the same place); ear plugs, eye masks and sunglasses for those with light and sound sensitivities; sleep hygiene measures; and avoidance of problematic foods and meditation.

Note: In addition to these basic treatments, disease experts have had success improving function in some patients by selectively using medications such as antivirals and immune modulators.

(*) This is not an exhaustive list of treatments. For further information on these and other treatments, see the references for the Adult and Pediatric Primers below.

5. Treat Comorbid Conditions

As listed earlier, a number of conditions may be comorbid with ME/CFS. Treating these comorbid conditions using the appropriate standard of care will not cure ME/CFS but it may improve the patient’s quality of life.
BASIC FACTS

- ME/CFS affects an estimated 836,000 to 2.5 million Americans but an estimated 84 to 91 percent of patients have not yet been diagnosed.
- ME/CFS affects 3 times as many women as men.
- Most patients currently diagnosed with ME/CFS are Caucasian, but some studies suggest ME/CFS is more common in minority groups.
- ME/CFS has been reported in patients younger than age 10 and older than age 70. Studies have shown one peak of onset between 11-19 and a second between 30-39.
- At least 25% of patients are bedbound or housebound and up to 75% are unable to work or attend school.
- Symptoms can persist for years, and most patients never regain their pre-disease functioning.
- ME/CFS costs the US $17 to $24 billion annually in lost productivity and direct medical costs.
- The cause of ME/CFS is unknown, although the disease often follows an infection.
